## **Executive Summary**

Environmental economists have seen their ideas translated into the rough-and-tumble policy world for over two decades. They have witnessed the application of economic instruments to several environmental issues, including preserving wetlands, lowering lead levels, and curbing acid rain. This essay examines the impact of the rise of economics in the policy world on the making of environmental policy. I focus on two related, but distinct phenomena – the increasing interest in the use of incentive-based mechanisms, such as tradable permits, to achieve environmental goals; and the increasing interest in the use of analytical tools in regulatory decision making, such as benefit-cost analysis.

I argue that economists and economic instruments play an increasingly important role in shaping environmental, health and safety regulation. Although the role of economics is becoming more prominent, it does not follow that environmental policy will become more efficient. This apparent inconsistency can be explained by the political economy of environmental policy.

# The Impact of Economics on Environmental Policy

Robert W. Hahn

## 1. Introduction

Many scholars dream about having their ideas put into practice. Yet, when the dream becomes a reality, it frequently feels different – in large part because of the gulf between the ivory tower and the real world. Environmental economists have seen their ideas translated into the rough-and-tumble policy world for over two decades. They have played an important role in shaping some key aspects of policy. They have, for example, witnessed the application of economic instruments to several environmental issues, including preserving wetlands, lowering lead levels, and curbing acid rain. Despite a few notable successes, the influence of economists on environmental policy to date has been modest.

I will focus on two related, but distinct phenomena – the increasing interest in using incentive-based mechanisms, such as tradable permits, for achieving environmental goals; and the increasing interest in using analytical tools in regulatory decision making, such as benefit-cost analysis.<sup>1</sup> For purposes of this essay, an *economic instrument* is defined as any instrument that is expected to increase economic efficiency relative to the status quo. This broad definition includes traditional incentive-based mechanisms, process reforms, and economic analysis that is used as a basis for designing more efficient policies.<sup>2</sup>

Economists can influence environmental policy in several ways. One is by advocating the use of particular tools for achieving better environmental outcomes through research, teaching, and outreach to policy makers. Another is by analyzing the benefits and costs of regulations and standards, which may demonstrate the inefficiencies of the goals themselves. A third way is by analyzing how decisions are made--by examining the political economy of environmental regulation. Each of these approaches can eventually have an impact on the different branches of government.

My thesis is that economists and economic instruments are playing an increasingly important role in shaping environmental, health and safety regulation. Although the role of economics is becoming more prominent, it does not follow that environmental policy will

---

<sup>1</sup>Other tools include cost-effectiveness analysis and risk-risk analysis. By risk-risk analysis, I mean an evaluation of potential increases in health risks that may arise from efforts to combat a targeted health risk. Such an evaluation can help decision makers compare policies (Lave, 1981). Farmers, for example, may increase the use of an equally toxic alternative pesticide if use of the original pesticide is restricted or banned to prevent drinking water contamination. For a more detailed description of risk-risk analysis, see Graham and Wiener (1995).

<sup>2</sup>The narrow definition of economic instruments is typically restricted to incentive-based mechanisms, such as emission taxes, deposit-refund schemes, tradable permits, subsidies, and removal of subsidies. Such mechanisms have the potential to achieve environmental outcomes at a lower cost than direct regulation. For a broader perspective on economic instruments that highlights the importance of transaction costs, see Richards (1998).

become more efficient. This apparent inconsistency can be explained by the political economy of environmental policy. I argue that economists need to do more than simply develop good ideas to influence policy. They need to understand how the political process affects outcomes, and more actively market the use of economic instruments as a means to make environmental policy more efficient.

Section 2 provides background on U.S. laws and regulations. Section 3 highlights the use of economic instruments in environmental policy.<sup>3</sup> Section 4 examines critical factors leading to the increased prominence of economics in environmental policy and also explains why economic efficiency is rarely central in environmental decision making. Section 5 summarizes the main arguments and suggests ways to enhance the impact of economists on environmental policy.

## 2. Laws, Regulations and the Need for Economic Instruments

Most environmental laws cover specific media, such as air, water, and land, and specific problems such as the control of toxic substances and the prevention of oil spills. They give rise to a staggering array of regulations requiring firms to obtain permits and meet specific requirements and guidelines. In some cases, firms must gain permission from federal or state authorities before making changes to production processes that have little or no impact on environmental quality.

There are now at least ten major U.S. federal laws that address environmental quality.<sup>4</sup> The largest in terms of estimated costs are the Clean Air Act (CAA), the Resource Conservation and Recovery Act (RCRA) and the Safe Drinking Water Act (SDWA).<sup>5</sup> According to the first comprehensive government report on the benefits and costs of federal regulation produced by the Office of Management and Budget, the direct costs of federally mandated environmental quality regulations in 1997 is approximately \$144 billion (OMB, 1997).<sup>6</sup> This is more than half

---

<sup>3</sup>I focus on the United States because that is the country with which I am most familiar; however, I believe the theses advanced in the paper are generally applicable to a wide range of developed countries as well as some developing countries.

<sup>4</sup>Consider the following laws that primarily the EPA administers: the Federal Insecticide, Fungicide, and Rodenticide Act, Clean Water Act, Clean Air Act, Resource Conservation and Recovery Act, Ocean Dumping Act, Safe Drinking Water Act, Toxic Substance Control Act, Comprehensive Environmental Response, Compensation, and Liability Act (Superfund), Emergency Planning and Community Right-To-Know Act, and Pollution Prevention Act. The list would be longer if it included laws not primarily under EPA's jurisdiction, such as the Endangered Species Act.

<sup>5</sup>According to the present value of compliance costs for final regulations published between 1982 and 1996, the CAA is the most burdensome with \$192 billion, second is RCRA with \$121.6 billion, and third is SDWA with \$43.6 billion in 1995 dollars (Hahn, 1998).

<sup>6</sup>Direct costs include the costs of capital equipment and labor needed to comply with a standard or regulation. Most of the cost estimates of individual regulations used by the OMB to calculate the aggregate costs only include direct costs, although a few also include indirect net changes in consumer and producer surplus. The OMB derives the aggregate cost estimate by using the EPA's estimate of the federally mandated compliance cost

of total federal government spending on all domestic discretionary programs.<sup>7</sup> Estimates of direct and indirect costs using general equilibrium approaches suggest that the costs are substantially higher (Hazilla and Kopp, 1990; Jorgenson and Wilcoxon, 1990).<sup>8</sup> The benefits from these laws are less certain than the costs. Some estimates suggest that aggregate benefits are in the neighborhood of costs (Freeman, 1990; OMB, 1997); others suggest they substantially exceed costs (U.S. EPA, 1997).<sup>9</sup>

The aggregate analysis of benefits and costs masks some important information on individual regulations, such as evidence that many environmental regulations would not pass a standard benefit-cost test. For example, more than two-thirds of the federal government's environmental quality regulations from 1980 to 1995 fail a strict benefit-cost test using the government's own numbers.<sup>10</sup> Indeed, if the government did not implement all major social regulations that failed a benefit-cost test during this period, net benefits would have increased by about \$300 billion (Hahn, 1998). Moreover, there is ample room to reallocate expenditures to save more lives at lower cost (Goklany, 1992; Morrall, 1986). A reallocation of mandated expenditures toward the regulations with the highest payoff to society could save as many as 60,000 more lives a year at no additional cost (Tengs and Graham, 1996).

For over two decades, economists have highlighted two significant problems with the current legal framework in U.S. environmental policy. The first is that the laws are overly prescriptive. Both laws and regulations frequently specify a preferred technology or set of technologies for achieving an outcome. For example, scrubbers were required for some power plants as part of a compromise reached under the 1977 Clean Air Act Amendments (Ackerman and Hassler, 1981). Economists have argued that a more flexible approach, such as an emissions tax, could achieve the same or similar environmental results at much lower cost (see, e.g., Bohm and Russell, 1985; Tietenberg, 1985). A second problem is that, while some statutes now require agencies to at least consider, if not balance, the benefits and costs of regulations, many laws still revolve around command-and-control regulation and contain no language to encourage agencies to balance costs and benefits (Crandall *et al.*, 1997; Portney, 1990). According to the courts interpretation of Section 109 of the Clean Air Act, for example, the

---

(EPA, 1990) as the baseline estimate for 1988 and adding the incremental costs from EPA's major regulations finalized between 1987 and 1996 (OMB, 1996). Unless otherwise stated, all dollar figures have been converted to 1996 dollars using the GDP implicit price deflator (Council of Economic Advisers, 1998).

<sup>7</sup>The total outlays in 1997 for domestic discretionary programs were \$258 billion (OMB, 1998). This figure does not include expenditures related to national defense or international affairs.

<sup>8</sup>Hazilla and Kopp (1990) find that although social costs were below EPA's compliance cost estimates in 1975, they exceeded compliance costs in the 1980's. This result is partially explained by people's substitution of leisure for direct consumption as a result of pollution control regulation, thereby decreasing output over time.

<sup>9</sup>The EPA estimates that the total benefits from the Clean Air Act between 1970 and 1990 are in the range of \$5.6 to \$49.4 trillion in 1990 dollars, while the direct compliance costs for the same period are \$0.5 trillion in 1990 dollars (EPA, 1997). For an insightful critique of the EPA's estimate, see Lutter (1998).

<sup>10</sup>Of the 70 final regulations analyzed, monetized benefits exceeded the costs in only 31 percent of EPA's rules (Hahn, 1998).

Environmental Protection Agency cannot consider the costs of determining national ambient air quality standards for designated pollutants. The result has been that many environmental programs and regulations have been put in place that would not pass a strict benefit-cost test. Both observations suggest that economic instruments could play a critical role in designing more efficient policies.

### 3. An Overview of Economic Instruments

It is useful to consider two categories of economic instruments for framing policy choices. The first includes *policies* whose purpose is to improve on the efficiency of the status quo. The second category consists of a group of analytical tools, such as benefit-cost analysis, whose aim is often to improve the economic efficiency of policies. The first category would include process reforms such as a regulatory budget, sunset provisions, peer review, requirements to evaluate alternatives to a regulation, and the provision of better information to Congress (Litan and Nordhaus, 1983). It would also include incentive-based mechanisms such as emission fees, tradable permits, deposit-refund schemes, direct subsidies, removal of subsidies with negative environmental impacts, reductions in market barriers, and performance standards.<sup>11</sup> The idea behind such instruments is that they create incentives for achieving particular goals that are welfare enhancing. Generally not included in this category are highly prescriptive technology-based standards. The second category includes benefit-cost analysis, cost-effectiveness analysis, and risk-risk analysis.

The preceding definition of economic instruments has the advantage that it includes a wide array of instruments, such as approaches to monitoring and enforcement, the use of the courts, and the use of information. One drawback is that, unlike the conventional definition, an instrument is not necessarily an economic instrument just because it is incentive-based. For example, an emission fee need not be an economic instrument using my definition if it leads to a reduction in economic efficiency. The definition used here requires the ability to specify a counterfactual – what would have happened in the absence of the application of a particular economic instrument – to determine how the policy would affect efficiency. I offer this definition because it seems natural that we should want economic instruments to improve economic efficiency.

Economists rarely frame the instrument choice problem in such general terms. Instead, they tend to focus on particular mechanisms, such as fees and permits, which are known to have efficiency-enhancing properties in theory. Below I examine these instruments, but also consider other instruments, including the increasing role of economic analysis in the formulation of environmental policy.

#### *The Increasing Use of Incentive-Based Mechanisms*

---

<sup>11</sup>See Stavins (1998) for a good overview of instrument types and their application. Kneese and Schultze (1975) provide an early treatment of some of the practical issues to consider in shifting to effluent taxes.

A broad array of incentive-based mechanisms has been used in U.S. federal environmental policy. Table 1 highlights some of the more important applications of fees, subsidies, tradable permits, and the provision of information. These mechanisms have been used for all media in a variety of applications.<sup>12</sup> Perhaps best known in terms of their potential for achieving cost savings are tradable permits. As can be seen from the table, their use has steadily increased over time at the federal level. Moreover, there has been increasing interest in the potential application of economic instruments as well (U.S. EPA, 1991).

The table shows that the ideas of economists regarding economic instruments are being taken seriously. President Clinton's 1993 Executive Order 12866 for Regulatory Planning and Review provides a good example. The order directs agencies to identify and assess incentive-based mechanisms, such as user fees and tradable permits, as an alternative to traditional command-and-control regulation, which provides less flexibility in achieving environmental goals.

The use of incentive-based mechanisms is also growing at the state level. Table 2 lists a sampling of state and regional programs. It shows that the use of these mechanisms is also increasing at the state level. There are now many programs at the regional level, such as Southern California's Regional Emissions Clean Air Incentives Market (RECLAIM) that allow polluters to trade emission allowances to achieve air pollution goals.

The interest in using incentive-based mechanisms is also growing in other countries. A survey by the Organization for Co-operation and Development (OECD) showed that, in 1992, twenty-one OECD countries had various fees and charges for emissions, twenty had fees and charges for specific high pollution products, sixteen countries had deposit-refund programs, and five countries had a tradable permit program (Opschoor *et al.*, 1994). Although the United States has predominantly used the tradable permits scheme at the federal level, European countries have more often used fees to help achieve their environmental goals. These fees typically have not had a direct effect on pollution because they have not been set at a level that directly affects behavior.<sup>13</sup>

In principle, the use of these mechanisms has the potential to achieve environmental objectives at the lowest cost. Many economic studies have projected cost savings from replacing the traditional command-and-control regulations with more flexible incentive-based regulations. A review of *ex ante* empirical studies on cost savings from achieving least-cost air pollution control pattern shows significant potential gains from incentive-based policies (Tietenberg, 1990). The ratio of costs from a traditional command-and-control approach to the least-cost policy for the eleven studies reviewed ranged from 1.07 to 22.00, with an average of 6.13.<sup>14</sup>

---

<sup>12</sup>This section focuses on efforts to improve environmental quality through pollution control measures, and does not review incentive-based mechanisms used in natural resource management. There are, however, notable initiatives at the state and federal level such as wetlands mitigation banking programs.

<sup>13</sup> Revenues from these fees, however, are often used to invest in improvements in environmental quality.

<sup>14</sup> These studies generally assume that a market-based approach will operate with maximum efficiency to

An aggregate savings estimate from all current incentive-based mechanisms for air, water, and land pollution control in the United States was developed by Anderson *et al.* (1997) using published estimates of potential savings and rough estimates where no studies were available. The authors estimate that in 1992, existing incentive-based programs saved \$11 billion over command-and-control approaches and will save over \$16 billion by the year 2000. This estimate includes significant state programs in addition to federal initiatives.

Although such an estimate provides a rough picture of the magnitude of potential cost savings, it does not provide an assessment of the actual cost savings. Many of the studies used to compile the estimate are based on *ex ante* simulations that assume incentive-based mechanisms achieve the optimal result. This is rarely the case in practice. Political obstacles frequently lead to markets that have high transaction costs and institutional barriers that reduce the potential for cost savings. Another problem with the estimation of savings is that it is difficult to assess what would have happened in the absence of a particular program. Even where cost savings are measured based on actual market data, it is not always clear if the program in question can be solely credited with the savings.<sup>15</sup>

There are three general categories of cost savings estimates for incentive-based mechanisms. The first is *ex ante* savings estimates that generally rely on simulations that assume the least cost abatement pattern is achieved. The second is *ex post* savings estimates that rely on market simulations similar to the *ex ante* estimates. The third is *ex post* savings estimates that use actual data from trades. Although there are a number of *ex ante* simulation studies of potential cost savings from achieving the least-cost pollution abatement scheme for various pollutants, there are relatively few *ex post* assessments of actual incentive-based programs and even fewer *ex post* assessments of actual cost savings. Table 3 highlights some of the problems with current knowledge of cost savings. The table shows *ex ante* and/or *ex post* estimates of cost savings for five tradable permit programs for air pollution control. I chose these programs since they represent programs where the most information is available; however, as the table shows, there are relatively few assessments of the actual impact of programs.

I was not able to find any *ex ante* assessments of the potential savings from the various parts of the Emissions Trading Program designed to reduce the cost of meeting air pollution regulation.<sup>16</sup> Hahn and Hester (1989) produced the only comprehensive study of costs savings based on actual trades. They estimated that the program achieved savings on the order of \$1.4 to \$19 billion over the first 14 years. These savings, however, do not represent the full extent of

---

achieve the same level of environmental quality at lower cost. In the real world, the counterfactual is less clear. It would be more realistic to compare actual command-and-control policies with actual market-based approaches (Hahn and Stavins, 1992).

<sup>15</sup> For example, railroad deregulation led to lower than expected prices for sulfur dioxide allowances by reducing the premium for low sulfur coal (Burtraw, 1996).

<sup>16</sup> For examples of early assessments of cost savings from using market-based approaches to achieve particular air pollution goals, see General Accounting Office (1982) and Tietenberg (1985).

potential cost savings. The program generally failed to create an active market for emission reduction credits, but it did allow for the environmental goals to be met at a lower cost (Hahn and Hester, 1989).

Lead trading, on the other hand, comes much closer to the economist's ideal for a smoothly functioning market. The EPA originally projected cost savings of \$310 million to refiners from the banking provision of the program between 1985 and 1987 (U.S. EPA, 1985). The actual cost savings may be much higher than anticipated since the level of banking was higher than EPA's expectations. There are no *ex post* estimates of cost savings based on actual trading.

There was at least one *ex ante* study of cost savings from using an incentive-based approach to curb the use of ozone depleting chemicals. The Rand study estimated that between 1980 and 1990, a price based incentive policy would save a total of \$143 million over a command-and-control approach (General Accounting Office, 1982). The EPA implemented an allowance trading program, and a tax on the ozone depleting chemicals was later added. Although the primary intent of the tax was to raise revenue, it may have been set high enough to have a significant incentive effect. The actual cost savings from the two approaches are unclear since there are no comprehensive *ex post* studies.

There have been some *ex ante* and *ex post* studies of the sulfur dioxide allowance trading program to reduce acid rain. *Ex ante* studies projected savings on the order of \$1 billion per year (ICF, 1992). The magnitude of actual cost savings achieved is estimated to be significantly less.<sup>17</sup>

The pattern of prices provides one indicator of cost savings, assuming that the marginal cost of abatement equals the price and total costs increase as marginal costs increase. In 1990, predictions of SO<sub>2</sub> permit prices were \$400 to \$1,000 per ton. The estimates from the beginning of the current phase of the program were significantly lower – between \$250 and \$400 per ton. Today actual SO<sub>2</sub> permit prices are about \$90 to \$110 per ton.<sup>18</sup> The discrepancy arises for a couple of reasons. First, early analyses did not include all provisions of the final bill such as the distribution of 3.5 million extra bonus allowances. The one estimate that included the extra allowances predicted prices of \$170 to \$200 per ton. Second, much of the remaining difference between predicted and actual permit prices is due to railroad deregulation, and the resulting fall in the price of low-sulfur coal (Burtraw, 1996).

Although the absolute savings that were projected have not materialized, relative savings are in the range of what was predicted by *ex ante* studies – approximately 25 to 35 percent of

---

<sup>17</sup> This discussion draws from Stavins (1998b).

<sup>18</sup> Actual incremental SO<sub>2</sub> abatement costs may be in the order of \$200 per ton. Permit prices are lower than abatement costs for three reasons. First, in the 1990 CAA Amendments, allowances are "not property rights," which means that the allowance would have a lower value than if they were a secure property right. Second, public utility commissions place restrictions on some utilities' ability to purchase permits, thus raising their abatement costs. Third, utilities may have believed early high price predictions, and so over invested in scrubbers.

costs absent trading (Ellerman *et al.* 1997, Carlson *et al.*, 1998). Interestingly, Burtraw (1996) has found that the primary source of cost savings was not directly from trading across utilities, but rather from the flexibility in choosing abatement strategies within utilities, which is consistent with earlier predictions. Therefore, improving the trading program may allow utilities to achieve further cost savings.<sup>19</sup>

The RECLAIM program in Southern California has received much attention over the last few years. The program was expected to produce significant cost savings. The South Coast Air Quality Management District (SCAQMD) had estimated that the program would yield cost savings of \$52 million in 1994 (Johnson and Pikelney, 1996). Although the potential savings are sizable and a review of the trading activity to date suggests significant cost savings have been achieved, there are no comprehensive studies that have assessed the actual savings.

As these examples show, the use of these mechanisms has increased and the potential savings are substantial; however, a more detailed review of these applications suggests that their performance has varied widely (Hahn and Hester, 1989). The variation in performance of these programs can be explained, in part, by differences in the underlying politics governing the choice and design of these programs. These political forces have led to policies that deviate from the economist's ideal.

Although the tradable permit schemes reviewed here did not exhaust cost savings, the programs generally improved environmental quality at a lower cost than alternatives under consideration. In contrast, the purpose of many environmental taxes and fees in the U.S. has been to raise revenue rather than reduce pollution. For example, the Superfund tax levied on crude oil, chemicals, and gross business profits is used to help finance cleanup. When fees have been levied directly on pollution, they have not been large enough to have significant impacts on behavior. Absent adequate incentives from fees, regulators have relied on command-and-control approaches to achieve desired levels of environmental protection. Thus, most environmental fees in the U.S. would not be economic instruments using the definition in this paper.<sup>20</sup>

The incentive based mechanisms considered above are primarily concerned with issues of cost-effectiveness -- that is, achieving a given goal at low cost. In contrast the regulatory analysis considered below addresses the choice of goals.

### *Moves Toward Analyzing the Benefits and Costs of Environmental Regulation*

To address the dramatic increase in regulatory activity beginning in the late 1960s, the past five Presidents have introduced mechanisms for overseeing regulations with varying

---

<sup>19</sup> However, these savings are likely to be less than the savings that accrue from intrautility trading (ICF, 1989).

<sup>20</sup> Some fees in Europe, such as Sweden's charge on nitrogen oxides from stationary sources, would be economic instruments (Smith and Vos, 1997).

degrees of success. A central component of later oversight mechanisms was formal economic analysis, which included benefit-cost analysis and cost-effectiveness analysis.

As a result of concerns that some environmental regulations were ineffective or too costly, President Nixon established a "Quality of Life" review of selected regulations in 1971. The review process, administered by OMB, required agencies issuing regulations affecting the environment, health, and safety to coordinate their activities. In 1974, President Ford formalized and broadened this review process in Executive Order 11281. Agencies were required to prepare inflationary impact statements of major rules. President Carter further strengthened regulatory oversight in 1978 by issuing Executive Order 12044, which required detailed regulatory analyses of proposed rules and centralized review by the Regulatory Analysis Review Group. This group consisted of representatives from the Executive Office of the President, including the Council of Economic Advisers, and regulatory agencies. A major focus of this review group was on environmental regulations such as the ozone standard, diesel particulate emissions, and heavy-duty truck emissions (White, 1981).

Since 1981, Presidents have required the use of regulatory impact analysis (RIA) for major regulations. President Reagan's Executive Order 12291 required an RIA for each "major" rule whose annual impact on the economy is estimated to exceed \$100 million (Smith, 1984).<sup>21</sup> The aim of this Executive Order was to develop more effective and less costly regulation. President Bush used the same Executive Order. President Clinton issued Executive Order 12866, which is similar to Reagan's order in terms of its analytical requirements but differs in terms of its stringency. Generally, the Executive Order directs agencies to choose the most cost-effective design of a regulation to achieve the regulatory objective, and to adopt a regulation only after balancing the costs and benefits. Unlike Reagan's order, however, Clinton's order requires agencies to promulgate regulations if the benefits "justify" the costs. This language is generally perceived as more flexible than Reagan's order, which required the benefits to "outweigh" the costs. Clinton's order requires a benefit-cost analysis for major regulations as well as an assessment of reasonably feasible alternatives to the planned regulation and a statement of why the planned regulation was chosen above the alternatives. Most of the major federal environmental, health and safety regulations that have been reviewed to date are promulgated by the EPA because those regulations tend to be the most expensive.

The Congress has been slower to support efforts to require the balancing of benefits and costs of major environmental regulations. In 1982 the Senate unanimously passed such a law, but it was defeated in the House of Representatives. The two primary environmental statutes that allowed the balancing of benefits and costs prior to the mid-1990s are the Toxic Substances Control Act and the Federal Insecticide, Fungicide, and Rodenticide Act (Fraas, 1991). Recently, Congress has shown greater interest in emphasizing the balancing of benefits and costs. Table 4 reviews recent regulatory reform initiatives, which could help improve

---

<sup>21</sup> While the definition of a "major" rule has changed somewhat over time, it is generally a regulation that is expected to have one or more of the following characteristics: an annual impact on the economy of \$100 million or more; a major increase in costs or prices for consumers or business; or significant effects on competition, employment, investment, productivity, or innovation.

environmental regulation and legislation. The table suggests that Congress now shares the concern of the Executive Branch that the regulatory system is in need of repair and could benefit from economic analysis (Crandall *et al.*, 1997). All reforms highlighted in the table emphasize a trend towards considering the benefits and costs of regulation, although the effectiveness of the provisions is as of yet unclear. Perhaps owing to the politicized nature of the debate over regulatory reform, these reform efforts have come about in a piecemeal fashion, and there is some overlap in the requirements for analysis.<sup>22</sup> These incremental efforts fall into the two categories of economic instruments described earlier in the paper: policies and analytical tools.

In the policy category, the Small Business Regulatory Enforcement Fairness Act of 1996 requires agencies to submit final regulations to Congress for review. The Telecommunications Act of 1996 requires the Federal Communications Commission to conduct a biennial review of all regulations promulgated under the Act. The regulatory accountability provisions of 1996, 1997, and 1998 require the Office of Management and Budget to assess the benefits and costs of existing federal regulatory programs and recommend programs or specific regulations to reform or eliminate. The OMB must report the results of its research in a report, released every one or two years depending on statutory requirements. The reports represent perhaps the most significant recent step towards strengthening the use of economic analysis in the regulatory process.<sup>23</sup>

The addition of statutory language to require the use of analytical tools has generally received more attention than the addition of policy reforms, partly because of their prominence in the Reagan and Clinton executive orders and partly because of controversy regarding their impact. The variation of the language and the choice of analytical tool for each of the statutes listed in Table 4 reflect the results of the ongoing controversy regarding analytical tools, which takes place every time Congress debates requiring their use. Some statutes require only cost-effectiveness analysis, some full-fledged benefit-cost analysis, and some combine some form of benefit-cost analysis with risk-risk analysis.

The Unfunded Mandates Reform Act of 1995 requires agencies to choose the “most cost-effective” alternative and to describe the costs and benefits of any unfunded mandate, but does not require the benefits of the mandate to justify the costs. The Safe Drinking Water Amendments of 1996 require the Administrator of the Environmental Protection Agency to determine whether the benefits justify the costs of a drinking water standard, but the Administrator does not have to set a new standard if the benefits do not justify the costs.<sup>24</sup>

---

<sup>22</sup> There has been some recent interest in Congress in reducing this overlap by establishing a single congressional agency that would have the responsibility for assessing the government regulation. This agency would be similar to the Congressional Budget Office, but have responsibility for regulation. It could help stimulate better analysis and review of agency rules by providing an additional source of information.

<sup>23</sup> Other examples in the policy category include the Paperwork Reduction Act, which sets measurable goals to reduce the regulatory burden, and the Government Performance and Results Act, which establishes requirements for agencies to develop mission statements, performance goals, and measures of performance.

<sup>24</sup> The Amendments also require some form of risk-risk analysis. They require the Administrator of the

Amendments in 1996 to the process through which the Secretary of Transportation sets gas pipeline safety standards, on the other hand, require the Secretary to propose a standard for pipeline safety *only* if the benefits justify the costs. Other statutes simply require the agency to only consider costs and benefits. The Food Quality Protection Act of 1996 is even more vague. The Act eliminates the Delaney Clause in the Food, Drug, and Cosmetic Act, the zero-tolerance standard for carcinogenic pesticide residues on processed food. Instead, the Administrator of the Environmental Protection Agency must set a tolerance level that is "safe", defined as "reasonable certainty of no harm." While the Food Quality Protection Act does not explicitly require the Administrator to consider benefits and costs when determining safe tolerance levels, the new language suggests increased balancing of costs and benefits relative to the original requirement. While the addition of such language to statutes represents an improvement over the status quo, it is clear that the major aims of the efforts to date have been to require more information on the benefits and costs of regulations and to increase oversight of regulatory activities and agency performance. Ensuring that regulations pass some form of a benefit-cost test has not been a priority.

There is evidence that states are also moving towards the systematic analysis of significant regulatory actions. According to a survey by the National Association on Administrative Rules Review (NAARR) in 1996, administrative law review officials in 27 states answered that their state statutes require an economic impact analysis for all proposed rules, and 10 states require benefit-cost analysis for all proposed rules.<sup>25</sup> Table 5 highlights efforts in six states. The first section describes efforts to review existing rules and procedures including any measures of success, and the second section describes the analysis requirements for new activities. While the efforts vary in their authority, coverage of activities, and amount of resources, they all place greater emphasis on economic analysis and the review of existing regulations and procedures. In addition, some states have begun to document the success of their efforts; however, the measures have generally been limited to the number of rules reviewed or eliminated. No estimates of actual welfare gains are available.

The use of RIAs is also increasing in other countries. Although the requirements for analysis and the structure of oversight vary from country to country, there are eighteen OECD countries, including the United States, that require some assessment of the impacts of their regulations (OECD, 1997). Although there is some anecdotal evidence of significant impacts RIAs have had on policy, the OECD study concluded that RIAs generally only have a "marginal

---

Environmental Protection Agency to set maximum levels for contaminants in drinking water at a "feasible" level, defined as feasible with the use of the best technology and treatment techniques available, while "taking cost into consideration." The Administrator must ignore the feasibility constraint if the feasible level would result in an increase in the concentration of other contaminants in drinking water or would interfere with the efficacy of treatment techniques used to comply with other national primary drinking water regulations. If the feasibility constraint does not apply, the Administrator must set the maximum level to minimize "the overall risk of adverse health effects by balancing the risk from the contaminant and the risk from other contaminants."

<sup>25</sup> All fifty states, except for Rhode Island, responded to a questionnaire sent by the NAARR (NAARR, 1996). Unfortunately, little is known about the level of compliance with these requirements, the quality of the analysis, and the influence it has on decision making.

influence" on decision making. Just as the review of U.S. federal experience with RIAs in Hahn (1996) showed inconsistencies in the quality of the analysis, the same pattern appears to exist in other countries.

The preceding discussion suggests that both incentive-based mechanisms and economic analysis are playing a more important role in environmental policy. One key challenge is to better understand the ways in which economics can influence the environmental policy debate.

#### 4. Understanding the Role of Economics and Economists in Shaping the Reforms

This section addresses the avenues through which economists have affected environmental policy, the limited influence of economics on policy, and the likely impact economists will have on future policy.

##### *Avenues of Impact*

There are three ways in which economists have influenced the debate over environmental policy – through research, teaching, and outreach.

The literature on economic instruments is voluminous and growing. There are three key ideas in the literature that have had an important impact on environmental policymaking: first, incentive-based instruments can help achieve goals at a lower cost than other instruments; second, benefit-cost analysis can provide a useful framework for decision making; and third, all policies and regulations have opportunity costs. Those ideas may seem obvious to economists, but they have not always been heeded in policy debates.

Economists have provided a normative framework for evaluating environmental policy and public goods (see, e.g., Samuelson, 1954; Baumol and Oates, 1988).<sup>26</sup> The literature on using incentive-based instruments to internalize externalities dates back to Pigou (1932), and for tradable permits, to Crocker (1966) and Dales (1968). The application of benefit-cost analysis to public projects begins with Eckstein (1958). Economists have also been helpful in comparing benefit-cost analysis with other frameworks for assessing the impacts of policies (see, e.g., Page, 1977; Lave, 1996).

Studies of incentive-based instruments have revealed that there are large potential cost savings from applying those instruments (Tietenberg, 1985). Moreover, economists have now marshaled some evidence of the potential cost savings of such systems in practice, as shown in Table 3.

The second way in which economists have translated their ideas into the policy process is by educating students who subsequently enter the world of policy and business. Many of those students embrace aspects of the economist's paradigm, in this case, as it applies to

---

<sup>26</sup> An excellent survey of the academic literature is provided by Cropper and Oates (1992).

environmental policy. Thus, for example, as more students in policy schools, business schools, and law schools are exposed to the idea of pollution taxes and tradable permits, it is more likely that they will consider applying economic ideas to particular problems, such as curbing acid rain and limiting greenhouse gas emissions.

Formal education is part of the *diffusion* process from the ivory tower to the policy world. Most major environmental groups, businesses, and agencies involved in environmental policy now have staff members with at least some graduate training in economics. Environmental advocates are more likely to support policies that embrace incentive-based mechanisms, and their advocacy is more likely to be couched in the language of economics. A comparison of today's debate over policy instruments for climate change with earlier debates on emission fees is revealing. In the seventies, emission fees were more likely to be viewed as "licenses to pollute." Today, most policy discussions on climate change identify the need for using incentive-based instruments to achieve goals in a cost-effective manner. The sea change in attitude toward the use of incentive-based instruments represents one of the major accomplishments of environmental economics over the last three decades.

A third, more direct way that economists have translated their ideas into policy is through policy outreach and advocacy. They have become increasingly effective "lobbyists for efficiency" (Kelman, 1981).<sup>27</sup> For example, my colleague, Robert Stavins, developed a very influential policy document that helped affect the course of the debate on acid rain by highlighting the potential for using incentive-based mechanisms (Stavins, 1988). Another example is the letter on climate change policy signed by over 2,500 economists (Arrow, Jorgenson, Krugman, Nordhaus and Solow, 1997). I have personally been involved in several efforts that developed a consensus among academics to help inform the broader policy community (Arrow *et al.*, 1996; Crandall *et al.*, 1997). The impact of such consensus documents, while difficult to measure, should not be underestimated.

To increase their influence on policy, economists may wish to think carefully about how they allocate their time among the activities discussed above. In terms of getting policies implemented effectively, it is generally not sufficient simply to develop a good idea. Some kind of marketing is necessary before the seedling can grow into a tree.

### *Limitations of Impact: Economics in the Broader Policy Process*

Economists, of course, are only one part of the environmental policy making puzzle. Politics affects the process in many ways that can block outcomes that would result in higher levels of economic welfare. Indeed, one of the primary lessons of the political economy of regulation is that economic efficiency is not likely to be a key objective in the design of policy (Noll, 1998; Becker, 1983).

---

<sup>27</sup> There are also a growing number of economic consultants and part-time consultants that may serve to impede the cause of efficiency (Noll, 1998).

Policy ideas can affect interest group positions directly, which can then affect the positions of key decision makers (such as elected officials and civil servants), who then structure policies through the passage of laws and regulations that meet their political objectives. Alternatively, ideas may influence decision makers directly.<sup>28</sup>

Policy proposals can help shape outcomes by expanding the production possibility frontier; however, the precise position on the frontier is determined by several factors. Take, for example, the design of incentive-based instruments for environmental protection (see, e.g., Hausker, 1992; Cason, 1993; and Franciosi *et al.*, 1993). Several scholars have argued that the actual design of economic instruments typically departs dramatically from the "efficient" design of such instruments for political reasons (see, e.g., Buchanan and Tullock, 1975; Maloney and McCormack, 1982; Keohane, Revesz and Stavins, 1998; Barthold, 1994). Frequently, taxes have been used to raise revenues rather than to reflect optimal damages (Hahn, 1989; Barthold, 1994). Standards have been made more stringent on new sources than old sources as a way of inhibiting growth in selected regions (Ackerman and Hassler, 1981); and agricultural interests have fought hard against the idea of transferable water rights because of concerns over losing a valuable entitlement. In some cases, the government has argued for a command-and-control approach when affected parties were ready to endorse a more flexible market-oriented approach. This was the case, for example, in the debate over restoring the Everglades (Passell, 1992). In short, rent-seeking and interest group politics have been shown to have a very important impact on the design of actual policy (Yandle, 1989).<sup>29</sup>

Political concerns affect not only the design of incentive-based instruments, but also the use and abuse of economic analysis in the political process. Notwithstanding such concerns, some scholars have argued that economic analysis has had a constructive impact on the policy process (Fraas, 1991; Morgenstern, 1997; Portney, 1998). In certain instances, research suggests that such optimism is justified; however, one must be careful about generalizing from a small sample. In many situations, analysis tends to get ignored or manipulated to achieve political ends. This is particularly true for environmental issues that have political saliency.<sup>30</sup> At the same time, by exposing such analysis to sunshine and serious reanalysis, there is a hope that politicians may be encouraged to pursue more efficient policies in some instances. My own experience suggests that analysis can help shape the debate in selected instances by making trade-offs clearer to decision makers.<sup>31</sup>

---

<sup>28</sup> In this discussion, the institutional environment (e.g., the three branches of government and the rules governing each branch) is taken as a given. Obviously, other ideas can affect the structure of those institutions.

<sup>29</sup> In addition, examination of particular rule making proceedings has shown the relative influence of particular factors in shaping environmental decisions (see, e.g., Magat, Krupnick and Harrington, 1986; Cropper, 1992).

<sup>30</sup> See, for example, the optimistic account of the cost to the U.S. of reducing greenhouse gases provided by the Council of Economic Advisers (Yellen, 1998).

<sup>31</sup> The impact of analysis on policy outcomes is not well understood; however, participants in the process can usually point to special cases where analysis was important. For example, in the clean air debate over alternative fuels, analysis of the cost and benefits of imposing of requiring companies to sell a large fraction of methanol-powered vehicles made this option look very unattractive.

The key point is that environmental economists should not be too optimistic about implementing some of their most fervently held professional beliefs in the real world. By improving their understanding of the constraints imposed by the political system, economists can help design more efficient policies that have a higher probability of being implemented.<sup>32</sup>

### *Likely Impact in the Future*

To understand the likely impact of economics on environmental policy in the future, it is helpful to understand the reasons for its importance in the past. A simple story is that federal environmental policy was initially designed without much regard to cost in the wake of Earth Day in 1970, which marked the beginning of an acute national awareness of environmental issues. As the costs increased and became more visible, and the goals became more ambitious, the constituencies opposing such regulation on economic grounds grew. Currently, the political (as opposed to economic) demands for environmental quality are high, but the costs are also high in many instances. This is an obvious situation in which economists can help by building more cost-effective mechanisms for achieving goals.

So far, environmental economists have enjoyed limited success in seeing their ideas translated into practice. That success is likely to continue in the future. In particular, there are likely to be more incentive-based mechanisms, greater use of benefit-cost analysis, and more careful consideration of the opportunity costs of such policies. But that does not mean that the overall net benefits of environmental policy will necessarily increase because the political forces that lead to less efficient environmental policy will still be strong.<sup>33</sup>

For those who believe benefit-cost analysis should play a more prominent role in decision making – in particular, the setting of goals – it will be a long, uphill struggle. The recent fight over the Regulatory Improvement Act of 1998 sponsored by Senators Levin and Thompson provides a good example. This bill essentially codifies the Executive Orders calling for benefit-cost analysis of major rules; yet, many within the environmental community are strongly opposed, arguing that it could lead to an analytical quagmire (Skrzycki, 1998; Hawkins and Wetstone, 1998). There are at least three reasons such opponents would take this stand. First, because making such claims is good for mobilizing financial support.<sup>34</sup> Second, because

---

<sup>32</sup> For example, in the debate over acid rain, it was clear there would be some implicit or explicit compensation to high sulfur coal interests. The challenge was to develop approaches that would maximize cost savings subject to that constraint.

<sup>33</sup> Environmentalists have been successful in framing the debate as being either "for" or "against" the environment, making it difficult to introduce the notion of explicit trade-offs. Their success is likely to continue for the foreseeable future.

<sup>34</sup> The 1994 Republican plan to repeal regulations, for example, breathed new life into the green movement. The highly-publicized plan resulted in a dramatic increase in memberships to environmental groups and an increase in donations by active members (The Economist, 1997). To the extent that benefit-costs analysis is perceived as a means to repeal regulations, opposing the use of such tools may have a similar revenue-enhancing effect.

of concerns that such legislation could help lead to more serious consideration of economics in environmental decision making. Third, opponents are concerned that agencies will misuse cost-benefit analysis and related analytical tools. In particular, there is concern with what will happen if politicians decide that cost is no longer a "four-letter" word – so that benefits and costs can be compared explicitly! Given the limited scope of this bill and the level of resistance encountered thus far, it is clear that the potential for change in the short term is limited.

The problem facing economists who want benefit-cost analysis to play a greater role in decision making is that it is difficult for politicians to oppose environmental laws and regulations simply because they may fail a benefit-cost test. After all, who could be against an environmental policy if it has some demonstrable benefits for some worthy constituency? It is hard to make arguments opposing such regulation in a ten-second soundbite on television.

But economists will continue to make slow progress in the area of balancing benefits and costs. In the short term, they will do so by making arguments about the potential for reallocating regulatory expenditures in ways that can save more lives or trees. Over the longer term, they will build a better information base that clearly shows that many environmental policies will pass a benefit-cost test if they are designed judiciously, but many also will not.

## 5. Concluding Thoughts

This paper has made a preliminary attempt to assess the impact of economics on environmental policy. There are at least three key points to be made about the nature of this impact. First, the impact often occurs with considerable time lags. Second, the introduction of economic instruments occurs in a political environment, which frequently has dramatic effects on the form and content of policy. Third, economists are not very close to a public policy heaven in which benefit-cost analysis plays a major role in shaping environmental policy decisions that governments view within their domain.

The latter topic concerning the appropriate domain for environmental policy may be one on which the profession contributes a great deal in the future. In particular, it is difficult to determine when it is "appropriate" for a particular level of government to intervene in the development of environmental policy (Oates and Schwab, 1988; Revesz, 1992). This is a subject on which there is a great deal of legitimate intellectual and political ferment. At one extreme, free market environmentalists wish to leave most, if not all, choices about such policy to the market (Anderson and Leal, 1992; Krier, 1992); At the other extreme some analysts believe there is a need for many levels of government intervention, including the design of a global environmental institution (see, e.g., Esty, 1994). Achieving some degree of consensus on that issue is likely to be difficult, but not impossible. For example, most economists agree that for global environmental problems, it is difficult to address them effectively without having some kind of international agency or agreement. At the same time, many economists recognize that the arguments suggesting competitive jurisdictions will under provide environmental amenities is somewhat weaker than was suggested two decades ago (see, e.g., Stewart, 1977).

Environmental economists will have many opportunities to shape the policy debate in new areas. Examples include international trade and the environment and the development of new taxation systems (Bhagwati, 1996; Kalt, 1989; Terkla, 1984 ; Goulder – find a cite that is appropriate.) One of the critical factors that will affect the rate of diffusion of ideas from environmental economists to the policy world is the *perception* of their success. If, for example, markets for environmental quality are viewed as a successful mechanism for achieving goals by both business and environmentalists, their future in the policymakers' tool chest looks brighter. The same can be said of benefit-cost analysis.

There are many challenges that lie ahead for the environmental economics community. The most important one is becoming more policy relevant.<sup>35</sup> To achieve that end, economists need to become more problem driven rather than tool driven. There seems to be a move in this direction, but there are also incentives in the profession that still push it in the opposite direction – most notably publish or perish.

Another challenge for the economics community is to determine how far it is willing to push the paradigm. Some would like government regulations, including environmental regulations, to at least pass a broadly defined benefit-cost test (Crandall *et al.*, 1997). Others more skeptical about the tool and less skeptical about the outcomes of certain kinds of government intervention, think economists and policy makers should not ask benefit-cost analysis to bear too much weight (see, e.g., Lave, 1996; and Bromley, 1990).

Finally, economists need to get more comfortable with the idea of being lobbyists for efficiency or advocates for policies in which they believe. This comfort level is increasing slowly. Moreover, economists are finding ways to institutionalize their power in certain policy settings. A good example is the Environmental Economics Advisory Committee within the Science Advisory Board at the Environmental Protection Agency. The primary function of that group is to help provide economic guidance to the agency on important regulatory issues. Now economists have a voice.

In sum, the impact of economists on environmental policy to date has been modest. Economists can claim credit for having helped changed the terms of the debate to include economic instruments—no small feat. They can also claim some credit for legislation that promotes greater balancing of costs and benefits. But specific victories of consequence are few and far between. Most of the day-to-day policy that real folks must address involves the activities associated with complying with standards, permits, guidelines and regulations. While economists have said a few intelligent things about such matters, their attention has been largely focused on those parts of environmental policy that they enjoy talking about—areas where

---

<sup>35</sup> It is possible that the influence of economics on environmental policy in developing countries may be greater because these countries have fewer resources to waste. That is, governments in developing countries may more likely use the tools advocated by economists to develop policies. While there are certainly many applications of economics in environmental policy in developing countries, the general thesis has yet to be demonstrated (see, e.g., Wheeler, 1998). Moreover, judging by the levels of inefficiency of other policies in developing countries, it is unclear why environmental policies may be designed more efficiently (see e.g., Bates, 1981).

theoretical economics can offer relatively clean insights. Perhaps if we expand our domain of inquiry judiciously and continue to teach tomorrow's decisionmakers, we can also expand our influence. Hope springs eternal.

<sup>1</sup> NA = Not Available

**Table 3: Estimates of Cost Savings over Command-and-Control Approach**

<b>Emissions Trading Program (1974- )</b>		
<i>ex ante</i>	No comprehensive studies on compliance cost savings.	
<i>ex post</i>	Total cost savings between 1974 and 1989 were between \$960 million to \$13 billion. "Netting" portion of the program was estimated to have saved \$25 million to \$300 million in permitting costs, and \$500 million to \$12 billion in emission control costs; "Bubbles" provision of the program was estimated to have saved \$300 million from federally approved trades, and \$135 million from state approved trades (1984 dollars).	Hahn and Hester (1989b)
<b>Lead Credit Trading (1982-1987)</b>		
<i>ex ante</i>	Refiners were expected to save approximately \$200 million over the 1985 to 1987 period (1983 dollars).	EPA (1985)
<i>ex post</i>	None thus far.	
<b>Ozone Depleting Chemicals Allowance Trading (1988- )</b>		
<i>ex ante</i>	The Rand study calculated that under an incentive based policy, the total compliance cost would be \$77 million, or roughly 40 percent, less than a command and control approach between 1980 and 1990 (1980 dollars).	Palmer <i>et al</i> (1980), as reported in GAO (1982)
<i>ex post</i>	None thus far.	
<b>Sulfur Dioxide Allowance Trading (1995- )</b>		
<i>ex ante</i>	\$689 million to \$973 million per year between 1993 and 2010 or 39 to 44 percent less than the costs without allowance cost trading (1990 dollars).	ICF (1992)
	Annual savings in 2002 is \$1.9 billion with internal trading, \$3.1 billion with interutility trading or 42 and 68 percent less than the cost absent trading (1992 dollars).	GAO (1994)
<i>ex post</i>	Total annual compliance cost savings in 2010 under the least cost approach is \$600 million or 35 percent less than the command and control approach (1995 dollars).	Carlson et al. (1998, forthcoming)
	\$225 to \$375 million dollars or 25 to 35 percent of compliance costs absent trading (1995 dollars).	Ellerman et al. (1997)
<b>RECLAIM (1994- )</b>		
<i>ex ante</i>	The RECLAIM program is expected to reduce compliance costs by \$38.2 million in 1994, \$97.8 million in 1995, \$46.6 million in 1996, \$32.9 million in 1997, \$67.7 million in 1998, and \$64.0 million in 1999 (1987 dollars). In the early years, the compliance costs are approximately 80 percent less than under a command and control approach, and close to 30 percent less in the later years.	Johnson and Pikelney (1996)
<i>ex post</i>	None thus far.	

**Table 4: Recent Regulatory Reform Legislation**

Legislation	Description
Unfunded Mandates Reform Act of 1995	Requires the Congressional Budget Office to estimate the direct costs of unfunded federal mandates with significant economic impacts. Requires agencies to describe the costs and benefits of the majority of such mandates. Requires agencies to identify alternatives to the proposed mandate and select the "least costly, most cost-effective, or least burdensome alternative" that achieves the desired social objective.
Small Business Regulatory Enforcement Fairness Act of 1996	Requires agencies to submit each final regulation with supporting analyses to Congress. Congress has sixty days to review major regulations, and can enact a joint resolution of disapproval to void the regulation if the resolution is passed and signed by the President. Strengthens judicial review provisions to hold agencies more accountable for the impacts of regulation on small entities.
Telecommunications Act of 1996	Allows the Federal Communications Commission to grant exemptions from regulations in certain cases and requires the consideration of the costs and benefits of specific provisions. Allows the Commission to grant waivers to buy-out prohibitions on local telephone companies if the anticompetitive effects are "clearly outweighed" by the benefits to the community of the transaction. Requires the Commission to conduct a biennial review of all regulations to determine whether any regulations are no longer necessary as a result of "meaningful economic competition" between providers.
Food Quality Protection Act of 1996	Eliminates the Delaney Clause of the Food, Drug, and Cosmetic Act, which set a zero-tolerance standard for pesticide residues on processed food. Establishes a "safe" tolerance level, defined as "a reasonable certainty of no harm." Allows the Administrator of the Environmental Protection Agency to modify the tolerance level if use of the pesticide protects consumers from health risks greater than the dietary risk from the residue, or if use is necessary to avoid a "significant disruption" of the food supply. Amends the Federal Insecticide, Fungicide, and Rodenticide Act by requiring a reevaluation of the safe tolerance level after the Administrator determines during the reregistration process whether a pesticide will present an "unreasonable risk to man or the environment, taking into account the economic, social, and environmental costs and benefits of the use of any pesticide."
Safe Drinking Water Act Amendments of 1996	Amends the procedure to set maximum contaminant levels for contaminants in public water supplies. Adds requirement to determine whether the benefits of the level justify the costs. Maintains feasibility standard for contaminant levels, unless feasible level would result in an increase in the concentration of other contaminants, or would interfere with the efficacy of treatment techniques used to comply with other national drinking water regulations. Requires the Administrator to set contaminant levels to minimize the overall risk of adverse health effects by balancing the risk from the contaminant and the risk from other contaminants in such cases.
Amended Gas Pipeline Safety Standards, 1996	Requires the Secretary of Transportation to consider the benefits and costs expected to result from implementation of a safety standard, and to propose a standard only if the benefits justify its costs. The benefit and cost estimates are based on a risk assessment, for which the Secretary must identify regulatory and nonregulatory options and must explain the selection of the standard in lieu of other options.
Regulatory Accountability Provisions	In separate appropriations legislation in 1996, 1997, and 1998, Congress required the Office of Management and Budget to submit an assessment of the annual benefits and costs of all existing federal regulatory programs to Congress for 1997, 1998, and 2000, respectively. The Office of Management and Budget already must review and approve analyses submitted by agencies estimating the costs and benefits of major proposed rules. The annual report provisions build on this review process.

**Table 5: State Efforts to Assess the Economic Impacts of Regulation**

	Review of Existing Rules		Analysis of New Rules			
	Initiated	Coverage	Examples of Results	Key Revisions <sup>3</sup>	Required Analysis	Requirement that Benefits Exceed Costs
Arizona	1986	Continuous (S) <sup>1</sup>	49% of 1,392 rules reviewed in FY 1996 were identified for modification.	1993	Economic impact (S)	All rules (S)
California	1995	One-time (E) <sup>2</sup>	3,900 regulations were identified for repeal; 1,700 were recommended for modification.	1991-1993, 1997	Economic impact (S, E)	Selected rules (S, E)
Massachusetts	1996	One-time (E)	Of the 1,595 regulations reviewed, 19% were identified for repeal and 44% were identified for modification.	1996	Economic impact (E)	All rules (E)
New York	1995	One-time (E)	In progress.	1995	Economic impact (S, E); Benefit-cost for selected rules (E)	All rules (E)
Pennsylvania	1996	One-time (E)	The Department of Environmental Protection identified 1,716 sections of regulations to be eliminated.	1996	Economic impact for selected rules (S); Benefit-cost for selected rules (E)	All rules (E)
Virginia	1994	Continuous (E)	Of the rules reviewed, 27% were identified for repeal and 40% for modification.	1994	Economic impact (S, E)	None

Source: Hahn (1998a)

<sup>1</sup>S = Statute

<sup>2</sup>E = Executive Order

<sup>3</sup>Although many of these states previously had some requirements for analysis of new rules, they resulted in cursory review. Important revisions were made through new executive orders and statutory changes to clarify and expand requirements and establish oversight.

## BELFER CENTER FOR SCIENCE AND INTERNATIONAL AFFAIRS

BCSIA is a vibrant and productive research community at Harvard's John F. Kennedy School of Government. Emphasizing the role of science and technology in the analysis of international affairs and in the shaping of foreign policy, it is the axis of work on international relations at Harvard University's John F. Kennedy School of Government. BCSIA has three fundamental issues: to anticipate emerging international problems, to identify practical solutions, and to galvanize policy-makers into action. These goals animate the work of all the Center's major programs.

The Center's Director is Graham Allison, former Dean of the Kennedy School. Stephen Nicoloro is Director of Finance and Operations.

BCSIA's International Security Program (ISP) is the home of the Center's core concern with security issues. It is directed by Steven E. Miller, who is also Editor-in-Chief of the journal, *International Security*.

The Strengthening Democratic Institutions (SDI) project works to catalyze international support for political and economic transformation in the former Soviet Union. SDI's Director is Graham Allison.

The Science, Technology, and Public Policy (STPP) program emphasizes public policy issues in which understanding of science, technology and systems of innovation is crucial. John Holdren, the STPP Director, is an expert in plasma physics, fusion energy technology, energy and resource options, global environmental problems, impacts of population growth, and international security and arms control.

The Environment and Natural Resources Program (ENRP) is the locus of interdisciplinary research on environmental policy issues. It is directed by Henry Lee, expert in energy and environment. Robert Stavins, expert in economics and environmental and resource policy issues, serves as ENRP's faculty chair.

The heart of the Center is its resident research staff: scholars and public policy practitioners, Kennedy School faculty members, and a multi-national and inter-disciplinary group of some two dozen pre-doctoral and post-doctoral research fellows. Their work is enriched by frequent seminars, workshops, conferences, speeches by international leaders and experts, and discussions with their colleagues from other Boston-area universities and research institutions and the Center's Harvard faculty affiliates. Alumni include many past and current government policy-makers. Libby Fellingner is BCSIA's Fellowship Coordinator.

The Center has an active publication program including the quarterly journal *International Security*, book and monograph series, and Discussion Papers. Members of the research staff also contribute frequently to other leading publications, advise the government, participate in special commissions, brief journalists, and share research results with both specialists and the public in a wide variety of ways.
